I. INTRODUCTION AND SUMMARY

Under an extension of Contract NAS 9-6978, a single repetitive diving/flying decompression table was evolved to enable astronauts to determine the surface intervals required, breathing either air or oxygen, before making a safe ascent to cabin pressure altitudes of 6, 8, 10, 12, 16, 20, or 24 thousand feet. The table considers hyperbaric exposures to air at depth increments of 0-12, 12-24, 24-36, and 36-47 feet of sea water (fsw)* for durations of up to 40, 80, and 120 minutes having a frequency of up to 2 exposures per day which are separated by surface intervals of at least 120, 180, or 240 minutes. It is assumed that these exposures may take place on every one of up to 5 successive days with an assumed surface interval of at least 16 hours between consecutive dives conducted on successive days. The diving/flying decompression table which was developed under Contract NAS 9-6978 states the required minimum preflight surface intervals in minutes breathing either air or 100% oxygen (administered by mask - a 2% N₂ mask leakage is assumed) after any number of repetitive hyperbaric exposures as delineated above.

The ascent-criteria (M-values) upon which this table is based were developed during a previous extension of this Contract. This work is described in Supplement A to our Final Report on Contract NAS 9-6978 (to be referred to as "Final Report" throughout this narrative).

Using our mathematical Tonawanda II Model of decompression (cf Final Report, p. 2) and the analyzed decompression experiences gained in 1553 manned altitude flights in its construction, we expected our repetitive diving/flying decompression table to be capable of predicting the outcome of experimental diving/flying exposures. Still we were impressed by the excellent agreement between safe preflight surface intervals predicted by our work and the safe surface intervals calculated on a theoretical basis

* A unit of pressure rigorously defined in the context of this study as being equal to $\frac{760}{33}$ Torr.

by Mr. P. O. Edel of the J and J Marine Diving Company, Inc. under Contract Number T-77650 with the National Aeronautics and Space Administration. This agreement serves to validate our modeling approach to decompression from depth as well as to altitude.

II. DESCRIPTION OF EFFORT

Using the computer program and decompression tables generated under the existing research effort, we constructed decompression tables which will predict safe surface intervals of crewmen who are subjected to diving exposure and then must fly.

In the preparation of the decompression tables, we took into consideration the following independent variables:

The hyperbaric exposures are made to depths ranging from 0-47 FSW. Calculations considered depth increments of 0-12 FSW, 12-24 FSW, 24-36 FSW and 36-47 FSW.

Duration of exposure varies from 20 min. to 2 hours. Calculations were based on exposures lasting 40, 80, and 120 minutes.

The frequency of exposures is to be a maximum of 2 exposures per day for up to 5 successive days. Two exposures during the day are to be separated by a period of surface pressure and varied from 2-4 hours. A surface interval of 16 hours is assumed to exist between pressure exposures on successive days. For calculation purposes, 2, 3, and 4 hour surface intervals were considered between exposures.

Air is the breathing mixture used during the dives and during the intervals on the surface between successive dives.

Both air and 100% oxygen (administered by mask) was considered as the breathing atmosphere to be used during the interval between the last dive and the flight.

The cabin pressure altitudes to be considered during the flight following the last dive are 6,000, 8,000, 12,000, 16,000, 20,000 and 24,000 feet. For all cabin pressures above 10,000 feet, it was assumed that 100% oxygen is breathed during the flight.

On the basis of the above independent variables, a table was constructed which will permit the astronaut or other involved personnel to determine (1) the duration of the surface interval, (2) the breathing mixture to be used, and (3) the maximum allowable cabin altitude that would be safe for a flight of 2 hours duration.

III. RESULTS AND DISCUSSION

Using the Gas Transport Equation (cf. Final Report, p. 11) and assuming instantaneous changes in the level of ambient pressure, a set of $\pi_{N_2}^{15}$ values at the end of the first day's second hyperbaric exposure and the corresponding $\pi_{N_2}^{15}$ values 16 hours later for each of the combinations of first exposure depths (12, 24, 36 and 47 FSW) and times (40, 80 and 120 min.), surface interval times (2, 3 and 4 hours) and second exposure depths and times was calculated.

An additional exposure depth of 0 FSW was included to allow for the possibility of a subject missing one or both of the two hyperbaric exposures on any of the five successive days. A unique five digit index was generated for each of the aforementioned combinations for purposes of identification only. The resulting $(4 + 1) \times 3 \times 3 \times (4 + 1) \times 3 = 675$ records were then arranged in ascending order based on the computed $\pi_{N_2}^{15}$ values prevailing 16 hours after the end of the second dive, and printed out. These values ranged from 25.11 FSW to a maximum of about 36.5 FSW. Each of these 675 values would become a starting $\pi_{N_2}^0$ value for the first dive on the following day and would in turn generate another 675 values for a total number of $(675)^5$ for a five day period of hyperbaric exposures at Huntsville.

Many of the various combinations of dive profiles and surface intervals were found to result in the same or nearly the same end-of-second-dive value of $\pi_{N_2}^{15}$. All of these values would fall between the starting value for the first dive and some maximum value. This maximum value was obtained by assuming repetitive dives to 47 FSW for 120 minutes each separated by a minimum rest period of 2 hours each day, and a minimum overnight surface interval of 16 hours.

<u>DAY</u>	<u>INITIAL $\pi_{N_2}^{15}$ VALUE</u>	<u>FINAL $\pi_{N_2}^{15}$ VALUE</u>	P ₀ (ground level) = 25.115 P ₀ (47 FSW) = 62.715
1	25.115	36.495	
2	27.414	37.757	
3	27.669	37.897	
4	27.698	37.913	
5	27.701	37.914	

The initial values of $\pi_{N_2}^{15}$ are those obtained following the 16 hour rest period while the final values are those computed at the end of the second exposure of the day. Hence, all $\pi_{N_2}^{15}$ values that could be encountered in this situation will fall between 25.115 and 37.914 FSW. Since there is no significant change in the final value of $\pi_{N_2}^{15}$ after the fourth day of maximum intensity diving, the mathematical development which follows is applicable to any number of successive diving days.

To classify each dive depth and time combination as a single activity, the following dive type numbers 1 through 15 have been assigned:

		DIVE TYPE NUMBERS		
MAXIMUM DIVE DEPTH IN FSW	0	1	2	3
	12	4	5	6
	24	7	8	9
	36	10	11	12
	47	13	14	15
MAXIMUM DIVE TIME IN MINUTES		40	80	120

Thus, for example, any dive to a depth greater than 24 FSW but equal to or less than 36 FSW for not more than 80 and not less than 41 minutes is classified as a dive type 11.

A table was constructed based on a single activity occurrence, since any one activity (dive or surface interval) consists of determining a new final $\pi_{N_2}^{15}$ value from the previous final $\pi_{N_2}^{15}$ value calculated. This table is presented as page i of Appendix I. It consists of final $\pi_{N_2}^{15}$ values resulting from the activity described by the column titles (denitrogenation of tissues for dive types 1, 2, and 3 and rest periods of 2, 3, 4 and 16 hours and nitrogen uptake for dive type 4 through 15).

The left most column of the table contains table line numbers. Immediately to the right of the line numbers are the initial $\pi_{N_2}^{15}$ values for the

current activity. These values were generated by stating initial $\pi_{N_2}^{15}$ values in increments of 0.15 FSW, so that the maximum spread of initial $\pi_{N_2}^{15}$ values possible could still be displayed by photo reduction on an 8 1/2 x 11 in. page. The first line entry of the table is the initial $\pi_{N_2}^{15}$ value of 25.115 FSW for the first exposure of the series to be conducted.

Use of the table can best be illustrated by an example. Assume the first day's schedule is to consist of a type 15 dive (47 FSW for 120 minutes), followed by a rest period of 3 hours, followed by a type 8 dive (24 FSW for 80 minutes). Starting with the initial entry of 25.11 FSW on line number 1, the tissue nitrogen tension of 31.93 FSW is extracted from the 1st line under dive type 15. This value becomes the starting tissue nitrogen tension for the surface interval of 3 hours which follows this dive. The value of 31.93 falls between the initial values of 31.86 and 32.01 FSW opposite line 46 and 47 respectively. To err on the conservative side, the value of 32.01 FSW on line 47 is chosen as the new initial value of $\pi_{N_2}^{15}$. Following line 47 to the right, the value of 30.23 is taken from the 3 hour Rest Period column. This in turn becomes the initial value of $\pi_{N_2}^{15}$ for the second hyperbaric exposure. Since 30.23 falls between 30.21 and 30.36 FSW the greater value, on line 36 is chosen. Following line 36 to the right, a final value of $\pi_{N_2}^{15}$ of 32.11 FSW is taken from the dive type 8 column. This then is the tissue nitrogen gas tension that must be considered if ascent to altitude is to follow this dive. When followed by another day's schedule, the value of 32.11 FSW is related to line 48 and a new $\pi_{N_2}^{15}$ value of 26.54 is obtained from the 16 hour Rest Period column. This value becomes the initial value for the next day's schedule and relates to line 11. Since any surface-level prebreathing period (delay time for tissue denitrogenation) required to effect safe ascents to altitudes of 6, 8, 12, 16, 20, and 24 thousand feet can be considered as just one additional activity, it was added to the second version of the table. Room was obtained for its inclusion by using the table line numbers as code numbers in place of the actual computed values of $\pi_{N_2}^{15}$. This table is presented as page ii of Appendix I.

The surface level prebreathing periods were computed by solving the Nitrogen Transport Equation (cf Final Report, Supplement A)

$$\frac{d\pi}{dt} = \frac{0.693}{416} (F_{I_{N_2}} [B-37] - \pi)$$

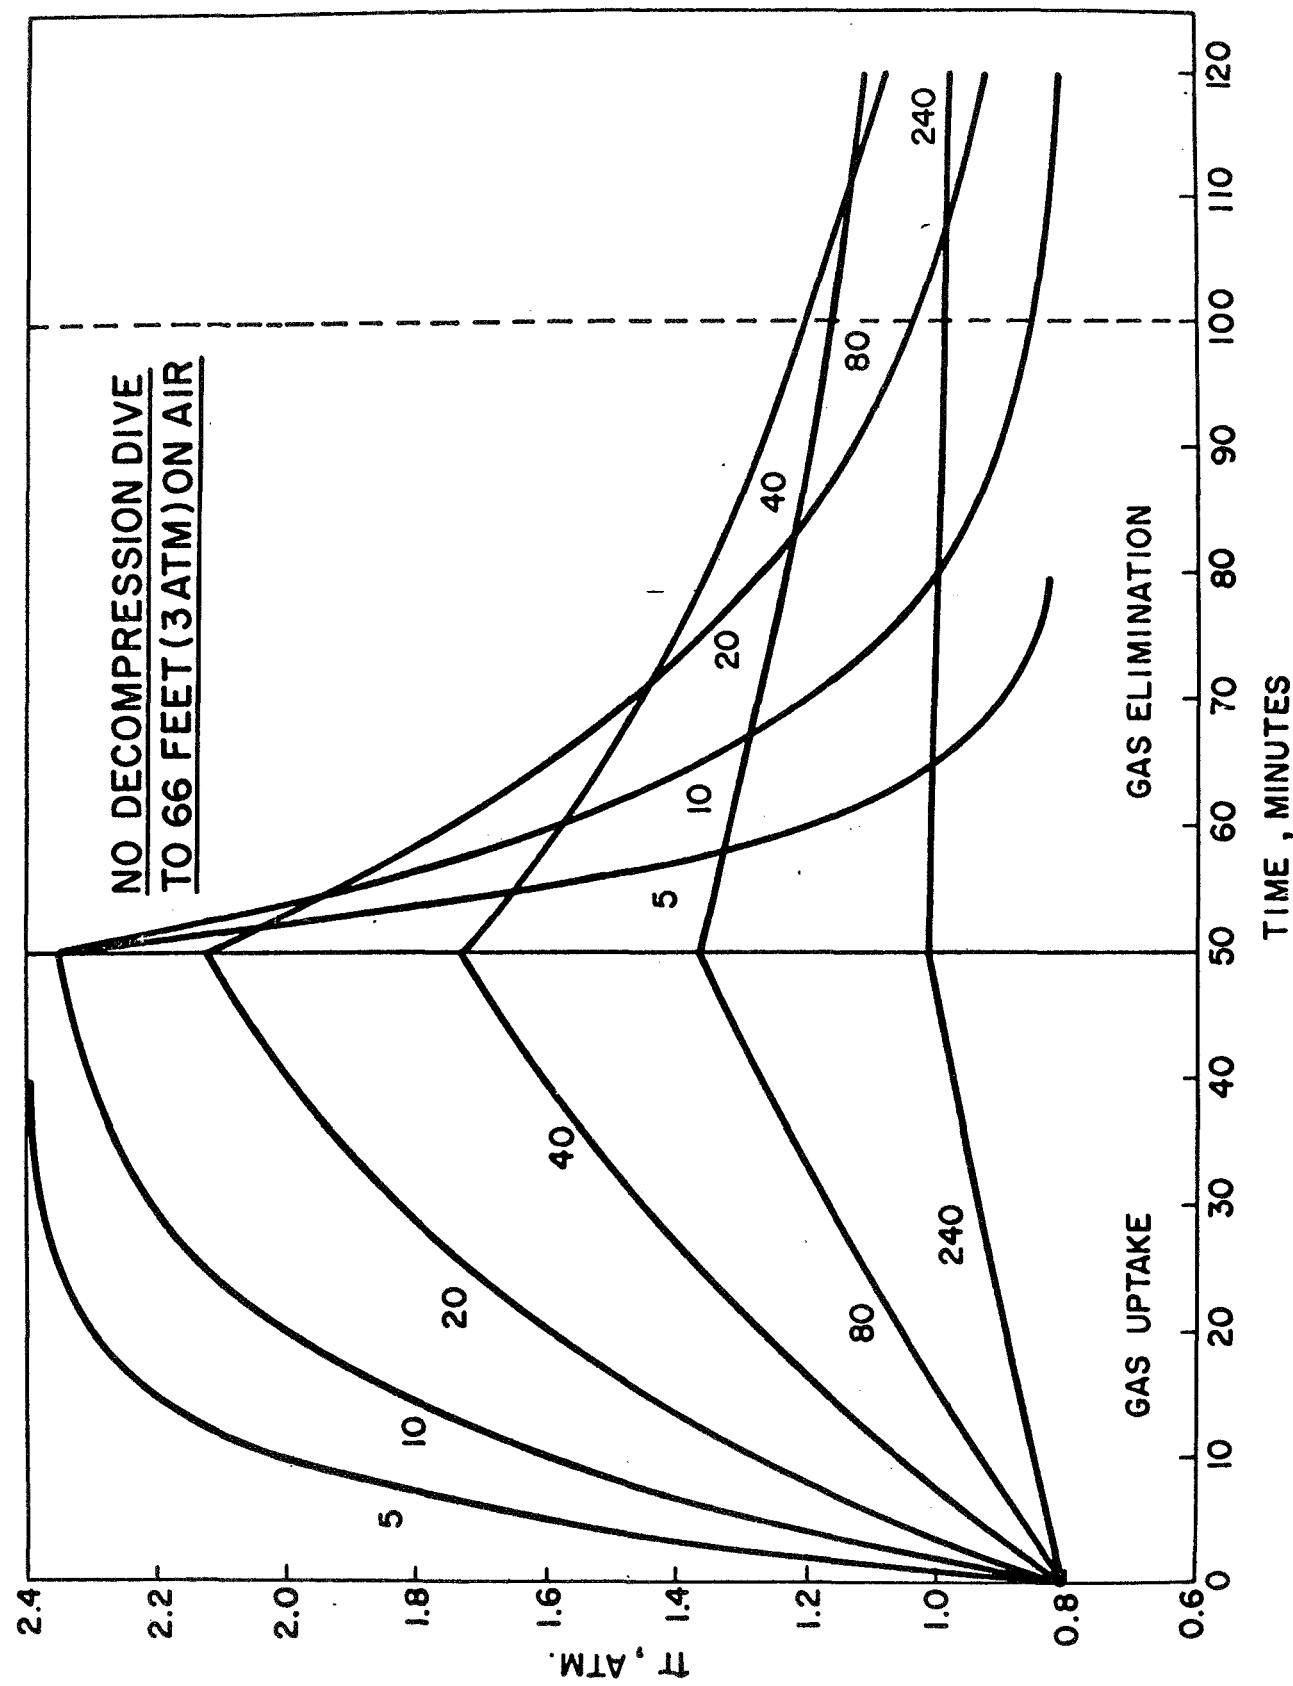

for t where $F_{I_{N_2}} = 0.80$ for air breathing and 0.02 for oxygen breathing by mask (assuring an average level of nitrogen in the mask due to inboard leakage of 2%), $B = 760$ mm Hg, π the ascent-limiting value of $\pi_{N_2}^{15}$ appropriate for a safe sojourn of 2 hours at a given target altitude (cf Final Report, Supplement A Table V) and π_0 the value of $\pi_{N_2}^{15}$ at the end of the last activity preceding the proposed flight as derived from page i of Appendix I.

Ascents to altitudes greater than 12,000 feet prebreathing air were not included in page ii of Appendix I since the M-value for the 15th compartment for safe ascent to 16,000 altitude is nearly equal to the inspired P_{N_2} value for surface breathing of air which produces lengthy prebreathing times, while $M_{N_2}^{15}$ values for safe ascent to 20 and 24 thousand feet cannot be attained by the ground-level breathing of air. Therefore oxygen prebreathing must be employed where necessary to insure the safe ascent to altitudes of 16,000 ft. and above.

Examination of the resulting table, indicated no air or oxygen prebreathing requirement for ascent to 6,000 ft. and only nominal prebreathing times for ascent to 8,000 ft. Whereas the preoxygenation times required for safe ascent to altitude from ground level (cf Final Report, Supplement A, Table VII) are based on the fact that only the slowest (15th) inert gas exchange compartment controls ascent, hyperbaric exposures could result in one of the faster inert gas exchange compartments being the controlling tissue during ascent to altitude. The gas uptake-gas elimination situation for a no decompression dive to 66 feet (3 Atm.) on air, illustrated in Figure 1, clearly indicates that such can be the case.

To overcome this weakness of our approach, a second table, included as page iii of Appendix I, was constructed assuming a "worst possible case" situation. Since maximum gas uptake takes place in the face of maximum

FIGURE 1

inspired inert gas pressure, we calculated the time (t) for a single 47 FSW exposure which would produce the value of $\pi_{N_2}^{15}$ listed on page i, Appendix I following the last hyperbaric exposure prior to ascent, a value that we would normally find in the left hand column of the table. Using this time we calculated corresponding values of $\pi_{N_2}^{15}$ for the remaining 14 inert gas exchange compartments of the Tonawanda II Model of decompression and then determined the length of time each compartment requires for sufficient nitrogen elimination to attain a desired $M_{N_2}^{15}$ value. The maximum time required is then reported as the required preflight ground-level interval regardless of which compartment is controlling. Lacking appropriate M-values for the other compartments, which usually are greater in value than that for the 15th compartment, we acted conservatively by using $M_{N_2}^{15}$ values for all 15 inert gas exchange compartments.

The tabular output (page iii, Appendix I) indicates that faster inert gas exchange compartments indeed control ascent to lower altitudes while the slowest (15th) compartment controls ascent to higher altitudes.

In tracing through this table, using dive types 15 and minimum surface intervals between daily dives of 120 minutes, we found that the tissue nitrogen tensions resulting from the 2nd exposure of the 3rd day, fell into an 88th category of $\pi_{N_2}^{15}$ values. Hence our repetitive diving/flying decompression table was expanded to contain 90 categories and is included as page iv of Appendix I.

A version of table iii in which ground-level air prebreathing times prior to ascent to 10,000 feet were displayed (page v, Appendix I) was used for comparison with diving/flying decompression data calculated by Mr. Peter O. Edel and reported by him in "Decompression Risks In Successive Hyperbaric-Hypobaric Exposures". This document reports work performed under contract number T-77650 with the National Aeronautics and Space Administration by J. and J. Marine Diving Company, Inc. This comparison relates to repetitive dives to 47 FSW for 120 minutes separated by a 3 hour surface interval and consecutive dives on succeeding days separated by a minimum surface interval of 16 hours.
